4x3 Matrix Keypad Interface - AVR Tutorial

Oct 13, 2010 Avinash AVR Tutorials 44

Many application requires large number of keys connected to a computing system. Example includes a PC keyboard, Cell Phone keypad and Calculators. If we connect a single key to MCU, we just connect it directly to i/o line. But we cannot connect, say 10 or 100 keys directly MCUs i/o. Because :-

It will eat up precious i/o line.

MCU to Keypad interface will contain lots of wires.

Buy Matrix Keypad

We want to avoid all these troubles so we use some clever technique. The technique is called multiplexed matrix keypad. In this technique keys are connected in a matrix (row/column) style as shown below.

Matrix Keypad Basic Connection

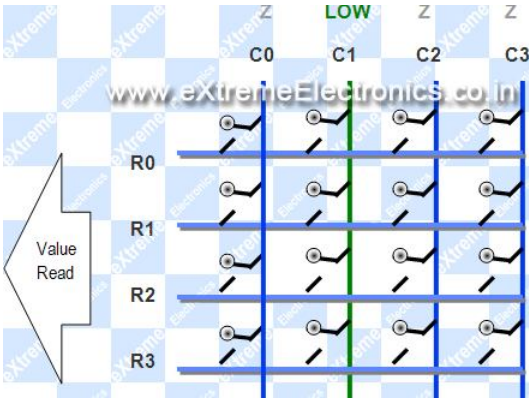
The rows R0 to R3 are connected to Input lines of Microcontroller. The i/o pins where they are connected are made Input. This is done by setting the proper DDR Register in AVR and TRIS Register in PIC. The column C0 to C3 are also connected to MCUs i/o line. These are kept at High Impedance State (AKA input), in high z state (z= impedance) state these pins are neither HIGH or LOW they are in TRISTATE. And in their PORT value we set them all as low, so as soon as we change their DDR bit to 1 they become output with value LOW.

One by One we make each Column LOW (from high Z state) and read state of R0 to R3.

Column 0 Selected

As you can see in the image above C0 is made LOW while all other Columns are in HIGH Z State. We can read the Value of R0 to R3 to get their pressed status. If they are high the button is NOT pressed. As we have enabled internal pullups on them, these pullups keep their value high when they are floating (that means NOT connected to anything). But when a key is pressed it is connected to LOW line from the column thus making it LOW.

After that we make the C0 High Z again and make C1 LOW. And read R0 to R3 again. This gives us status of the second column of keys. Similarly we scan all columns.



Column 1 Selected

How to Do it All with AVRs

Each i/o port in AVR has three related registers PORTx, DDRx and PINx. For example port A has

PORTA Port Driver - when any bit is set to 1 it appears as HIGH i.e. 5v . But this is the case only if that bit is OUTPUT. If it is input, setting any bit to 1 enables the internal pullup on that bit.

DDRA DATA DIRECTION REGISTER - Make any pin on than port as IN or OUT. When bit is 1 it represents Output. When bit is 0 it represents Input. Input state is also called tristate or high Z state.

PINA - Read it to get the level (HIGH or LOW) at the actual i/o pin. It is read when the pin is made input.

So now you know

How to make any i/o line Input(high Z) or Output.

How to enable internal pullup register on input lines.

How to read value that is present on input lines.

Please see the following tutorial for more clarification.

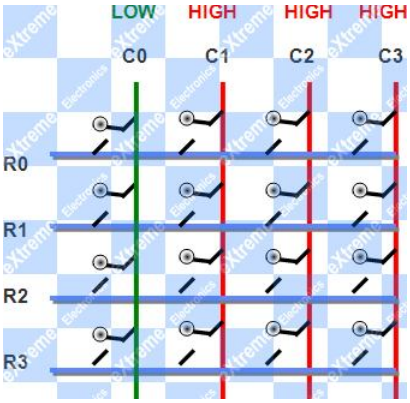
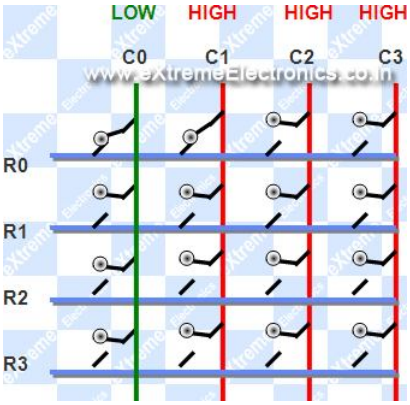
Why we make other Columns High Impedance while one column is made LOW?

Lets say we selected column number C0, so we make it LOW(i.e. GND or logic 0), in the same time we make all other columns high impedance (i.e. input). If we don't make other lines high impedance (tristate or Input) they are in output mode. And in output mode they must be either LOW(GND or logic 0) or HIGH (5v or logic 1). We can't make other lines LOW as we can select only one line at a time and C0 is already low as per assumption. So the only other possible state is all other columns are HIGH. This is shown in figure below. Red colour on column indicate high state while green is for low state.



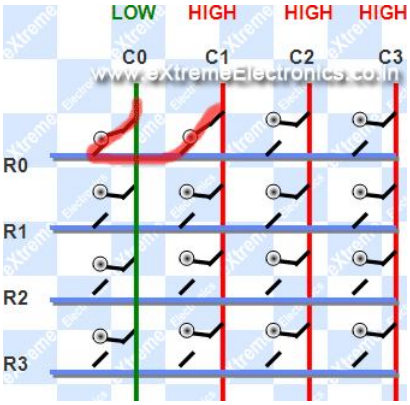
Wrong Way!

Suppose at that time the user presses KEY0 and KEY1 simultaneously as shown below.



Short Circuit !

As you can see clearly that it create a short between C0 (GND) and C1 (5v), this will burn out the buffer of the MCU immediately!



Short!

That's why all other columns are kept at tristate(neither LOW nor HIGH) but very high input impedance that prevent either source or sink of current from them. So if we kept C1 at high impedance state it wont allow current to flow to GND on C0.

avr-gcc C code for 4x3 matrix keypad

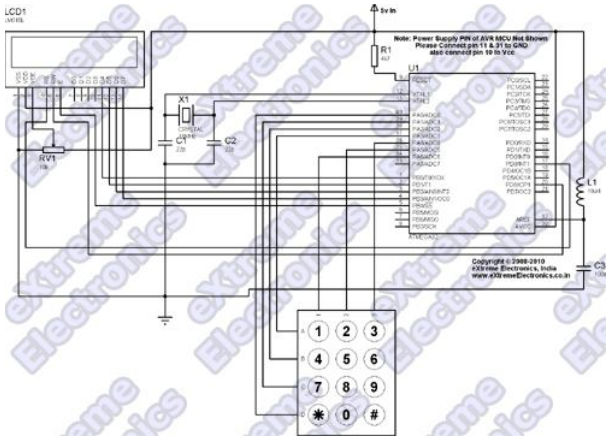
The above code make use of the LCD Library. You can get more information on LCD Library here :-

http://extremeelectronics.co.in/avr-tutorials/using-lcd-module-with-avrs/

Hardware for 4x3 Matrix Keypad and AVR interface.

The test circuit will be built around **ATmega32 microcontroller**. The output device will be a **16x2 lcd module**. So we set up a basic ATmega32 circuit. The circuit will have the following :-

1. ATmega32 MCU
2. 16MHz Crystal
3. Reset Circuit.
4. 5v Power Supply Circuit.
5. ISP (For programming)
6. LCD Module.
7. LCD Module Contrast adjust pot.



ATmega32 + LCD + Keypad Interface.

We have built the above circuit on a **Low Cost AVR Development Board**, but it does not has inbuilt LCD Module connector so you need to solder it yourself at the free area (and also do the wiring).

Compile the above program using AVR Studio (compiler is avr-gcc). And finally burn the program using any **ISP Programmer** to the ATmega32. **The fuse bits must be set as following to enable external crystal as clock source.**

High Fuse = C9 (hex value)

Low fuse =FF (hex value)

After burning the HEX file to MCU, finally you are ready to power up the setup. **When powered on, the LCD Screen Should show you the keycode of the key pressed on the keypad.** This complete our test.

Troubleshooting

NO Display on LCD

Make sure AVR Studio Project is set up for clock frequency of **16MHz** (16000000Hz)

Adjust the Contrast Adj Pot.

Press reset few times.

Power On/Off few times.

Connect the LCD only as shown on schematic above.

No response to key press.

Check that keypad is connected on PORTA only.

If you want to attach keypad on different port, change the line 80 on source code (keypad.c)

```
#define KEYPAD A //KEYPAD IS ATTACHED ON PORTA
```

Compiler Errors

1. Many people these days has jumped to embedded programming without a solid concept of computer science and programming. They don't know the basics of compiler and lack experience. To learn basic of compilers and their working PC/MAC/Linux(I mean a desktop or laptop) are great platform. But embedded system is **not good** for learning about compilers and programming basics. **It is for those who already have these skills and just want to apply it.**
2. Make sure all files belonging to the LCD Library are "added" to the "Project".
3. avr-gcc is installed. (The Windows Binary Distribution is called **WinAVR**)
4. The AVR Studio project Type is AVR GCC.

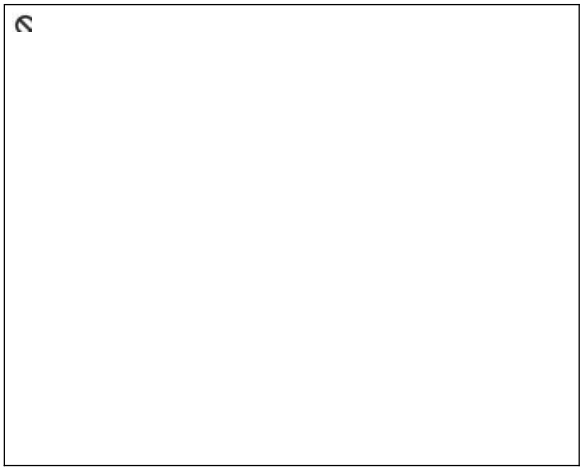
5. Basics of Installing and using AVR Studio with avr-gcc is described in this **tutorial**
6. How to add files to project is described in this **tutorial.**

General Tips for newbies

Use ready made **development boards** and **programmers**.

Try to follow the AVR Tutorial Series from the very beginning. (Remember the list spans four pages, page 1 is most recent addition thus most advance)

Video For 4x3 Keypad Interfacing.



User Videos

By Brendin

I really appreciate Brendin's approach on getting his problem solved and successfully porting the demo to ATmega48. What I recommend the users is to get your basics strong. You need full understanding of C language concept and the full details of the device you are programming, this will save you lots of time. So please go and read the good book on C and the datasheet of AVRs before you dive in! - ***Avinash***

Downloads

AVR Studio Project For 4x3 Keypad Interface.

VMLab simulation project : VMLAB is a very good free simulator for AVR's, you can use it to simulate the above circuit without making any hardware. Simply load "my_idea.prj" (available in the above package) in VMLab.

Proteus VSM Simulation Project.

HEX Code for 4x3 Keypad Interface.

Help Us!

We try to publish beginner friendly tutorials for latest subjects in embedded system as fast as we can. If you like these tutorials and they have helped you solve problems, please help us in return. **You can donate any amount as you like securely using a Credit or Debit Card or Paypal**.

We would be very thankful for your kind help.

October 16, 2010 at 12:29 pm

Hi Avinash,
great tutorial again, but you diddnt add the .c file as a part of the download. It would have helped to find out how your program actually works!!
Regards,
Mayukh.

Hi Avinash,
the objective was to remove my confusion!! When i checked ur site, i didd'nt see the first link under downloads (which does not necessarily mean it was not there). I wanted to compare my code (for a 4×4 kpad) with yours (keeping yours as referance) as my approach for scanning the keys was somewhat different, making use of one loop and without the shifting.
Regards,
Mayukh.

Great tutorial. Could this be adapted for my atmega48 mcu? I was able to get the LCD tutorial to compile for the 48 but this one won't build.

Build started 19.10.2010 at 17:05:01
avr-gcc -mmcu=atmega48 -Wall -gdwarf-2 -std=gnu99 -DF_CPU=16000000UL -O2 -funsigned-char -funsigned-bitfields -fpack-struct -fshort-enums -MD -MP -MT Keypad.o -MF dep/Keypad.o.d -c ../Keypad.c
../Keypad.c: In function 'GetKeyPressed':
../Keypad.c:117: error: 'PORTA' undeclared (first use in this function)
../Keypad.c:117: error: (Each undeclared identifier is reported only once
../Keypad.c:117: error: for each function it appears in.)
../Keypad.c:121: error: 'DDRA' undeclared (first use in this function)
../Keypad.c:126: error: 'PINA' undeclared (first use in this function)
../Keypad.c: At top level:
../Keypad.c:137: warning: return type of 'main' is not 'int'
make: *** [Keypad.o] Error 1
Build failed with 5 errors and 1 warnings…

Sorry…but I got it to compile…I just needed to change to Keypad.c to use PORT B.

#define KEYPAD B //KEYPAD IS ATTACHED ON PORTA

I will try and breadboard it and see if it works.

Reply ↓

5. Brendin
October 20, 2010 at 6:47 am

I got it working on the atmega48. I needed to also set the reset pin disable to set PC6 as I/O (this unfortunately means I can no longer program with the ISP programmer). The code works for every button except 2 and 3 (using a 4×3 keypad 2 and 3 are equivalent to 2nd and 3rd button on the top row in this tutorial). When I hold down the 2 button the LCD flashes between 0 and 1 very fast. When I hold down 3 button the same thing happens but flashes between 0 and 2. All the other buttons work properly

I am not using an external clock. Fuse settings are Low=E2 High=5F and Extended=FF

What would cause this?

thanks,
Brendin

6. Brendin
October 20, 2010 at 8:27 am

I changed some things around and got it working. I put the lcd data on port C and the keypad on port B. Now I don't have to worry about setting port c6 as an input and disabling reset. All of the keys output as expected. Here is a youtube link.

http://www.youtube.com/watch?v=7buBfN0kn04

Changes I made

lcd.h
/***
LCD CONNECTIONS
***/

#define LCD_DATA C //Port PB0 TO PB3 are connected to D4-D7

#define LCD_E C //Enable/strobe signal
#define LCD_E_POS PC4 // PB4 Position of enable in above port

Keypad.c
#define KEYPAD B //KEYPAD IS ATTACHED ON PORTA

Hi Avinash

I have interfaced a 4×4 keypad using atmega32 and I face similar problems as Brendin. I mean, whenever I press the 2nd, 3rd and 4th keys, the display flashes between 0 and 1, 0 and 2, 0 and 3 respectively. Unlike his case, the problem did not solve by changing the ports…

Reply ↓

13. Sinet Rags

September 15, 2011 at 10:14 am

@Avinash

I understand ur point of view …. but if a person has already got a toy car , all opened up then why hesitate in experimenting. If u have time can u atleast tell how can i connect an AtmegaXX to the RF toy car circuit … Correct me if i am wrong anywhere ….

Another question is how can i increase aerial data transfer range if i bought a RF module, for, currently i noe its limited to a modest span of some feet. Cuz elec.mag waves can propagate long distances.

Is it achieved with the aid of repeaters (Power Boosting). And if i dont have repeaters(non commercial experimentation) then how can i increase range of RF module by increasing its Power i/p .

Reply ↓

14.  Avinash Post author

September 15, 2011 at 10:20 am

@Sinet Rags,

Their are various RF Toy car in the market. Each one has a module made specially for that car.

Even the cheapest RF module works great at-least giving 50 feet range in full urban environment.

If your is giving only few feets then their may be series design fault in your designs.

17. Rahul Ch

Hi Avinash,

As Brendin said that to use PC6 as input we have to disable RESET. Then,
1. How can we program AVR in such cases?
2. Whenever, I use PC6 as output, on pressing the
RESET switch, how does RESET gets activated,or,
what happens internally??? Does it generate some
kind of interrpt???
3. Somedays ago in a wireless robo-boat championship I
saw that none of the boats were working.
All the boats had RF modules attached all of the
same frequency, but DIFFERENT ADDRESS BITS set in
the Rx and Tx. Can you explain? Is it because all
of them were trying to work at the same frequency?
If yes, Why are address bits provided in Rx and Tx
modules using a DIP switch……..

Thank You in advance

Reply ↓

21. Tamilvanan.A
April 6, 2012 at 10:11 am

The program works no doubt in that.

But, you might encounter some key malfunctioning problems if you don't add a 1ms or 2ms delay before reading the inputs especially when you are running at 16MHz.

It's always advisable to add a 1ms or 2ms delay after you change the state of the port pins before reading.

If anybody encounters a problem with interfacing with the above program, kindly add '_delay_ms(1);' in line 122 and between lines 123 and 124. If problem persists increase the delay to 2ms.
